Network Log Analysis

DG Interns Hub - Week 3 | **Name: Harini E | Intern ID: DG/15/OCT/CYBER/040**

Platform	LetsDefend (free course, SOC Analyst Learning Path)
Course	Network Log Analysis
Status	Completed as part of my Week 3 work

Overview

This course is about the network log sources a SOC analyst examines during an investigation. Network logs record which machines talked to each other, over which ports and when, so they are a key source of evidence when a host or a user is under suspicion. I took it in the same week I worked with Snort, which produces network alerts that an analyst reads in the same way.

Ideas I connect with this course

Idea	In short
What network logs show	Source and destination addresses, ports and times, so an analyst can see who connected to what.
Different log sources	Logs from a firewall, a proxy, DNS or an IDS see traffic from different points, so more than one source is often needed.
Network and endpoint together	A network log shows the connection, and an endpoint log such as Sysmon Event ID 3 shows which process made it.

What I took from it

Network logs are most useful when they are read together with other evidence. In my own lab, the Snort alerts showed the scan reaching the machine, and the Sysmon and auditd records showed what happened on the machines themselves. Seeing both sides is what lets an analyst reach a confident conclusion.
