Incident Response on Linux

DG Interns Hub - Week 3 | **Name: Harini E | Intern ID: DG/15/OCT/CYBER/040**

Platform	LetsDefend (free course)
Course	Incident Response on Linux
Level / role	Medium, Incident Responder
Status	Completed as part of my Week 3 work

Overview

This course covers how to detect, analyse and deal with security threats on Linux systems. It is aimed at system administrators, incident responders and security analysts, and it needs a basic understanding of Linux and general cybersecurity. I took it because I worked on Linux logging this week, with auditd on my Ubuntu machine.

Topics in the course

Topic	In short
How to Create an Incident Response Plan	Incident response is a systematic way of managing a security incident, and a plan with several stages (starting with preparation) helps a team handle it in an organised way.
Useful Log Files	The Linux log files an analyst checks during an incident, such as the authentication and system logs I covered in my theory notes.
.bashrc and .bash_profile	Files that run when a user starts a shell. They are worth checking, since an attacker can add commands there to run again later.

What I took from it

On Linux, the first things to look at are the logs and the user startup files, and a clear plan decides what to do first. This connects to my auditd work this week: auditd gave me the record of which command was run, by which user, and from which terminal, which is the kind of evidence an incident responder needs.
